Enterprise Interaction Management

CONFIDENTIAL 1

What is the “activity service”?

- ❑ Additional Structuring mechanisms for the OTS
 - ☒ OMG adopted specification (orbos/2000-06-19)
 - ◎ IBM, University of Newcastle (Bluestone Arjuna Labs), IONA, Inria, Alcatel, Vertel/Expersoft, Bank of America
- ❑ Main work provided by IBM and Newcastle University
 - ☒ 12+ months to develop and guide through OMG process
- ❑ Inria provided an example of use

Problem statement

- ❑ Transactions imply all ACID properties
- ❑ Good for “short” durations
 - ☐ Application specific
- ❑ Long-running transactions may impose constraints
 - ☐ Hours, days, months, ...
 - ☐ Retain resources for duration of transaction
- ❑ Should build on existing transaction standard

Structuring transactions

- ❏ Could structure transactional applications from short-duration transactions
 - ☐ Release locks early
 - ☐ Resulting application may still be required to appear to have “ACID” properties
 - 🎯 May require application specific means to restore consistency
- ❏ A transactional workflow system could be used to script the composition of these transactions

Extended transaction models

- There are a number of such models
 - Sagas
 - Compensations
 - Epsilon Serialisability
 - Versioning Schemes
 - Nested top-level transactions
 - Open-nested transactions
 - Glued transactions
 - Coloured actions

Which model to use?

- ❑ One size does not fit all!
- ❑ Business domains will impose different requirements on implementers
 - ☐ Essentially construct domain-specific models
 - ☐ Realtime
- ❑ The range and requirements for such extended models are not yet known
 - ☐ Do not restrict implementations because we don't know what we want yet!

Basic assumptions

- ❏ Models share a basic underlying assumption of “event signalling”
 - ☒ Specific model maps event into its “domain”
 - 🎯 e.g., “prepare”, “rollback”
- ❏ OTS transactions may be used as building blocks
 - ☒ Transactions may be ignored if required
- ❏ Some level of interoperability between models may be possible
 - ☒ Signal-mapping

CosActivity module

- ❑ Defines a generic protocol engine
 - ☐ Support basic infrastructure for many extended models
- ❑ Pluggable coordination and control engine
- ❑ Activity service interfaces not typically for application programmers
 - ☐ Too low-level
 - ☐ Requires high-level API on top

Activities

- ❑ Activity is an entity that does some work
 - ☑ Activities can be nested
 - ☑ May use transactions during parts of its lifetime
- ❑ Ensure transaction contexts (and extended context data) flow between address spaces
- ❑ Threads can run within activity context as well as transaction context
- ❑ Recoverable

Activities and transactions

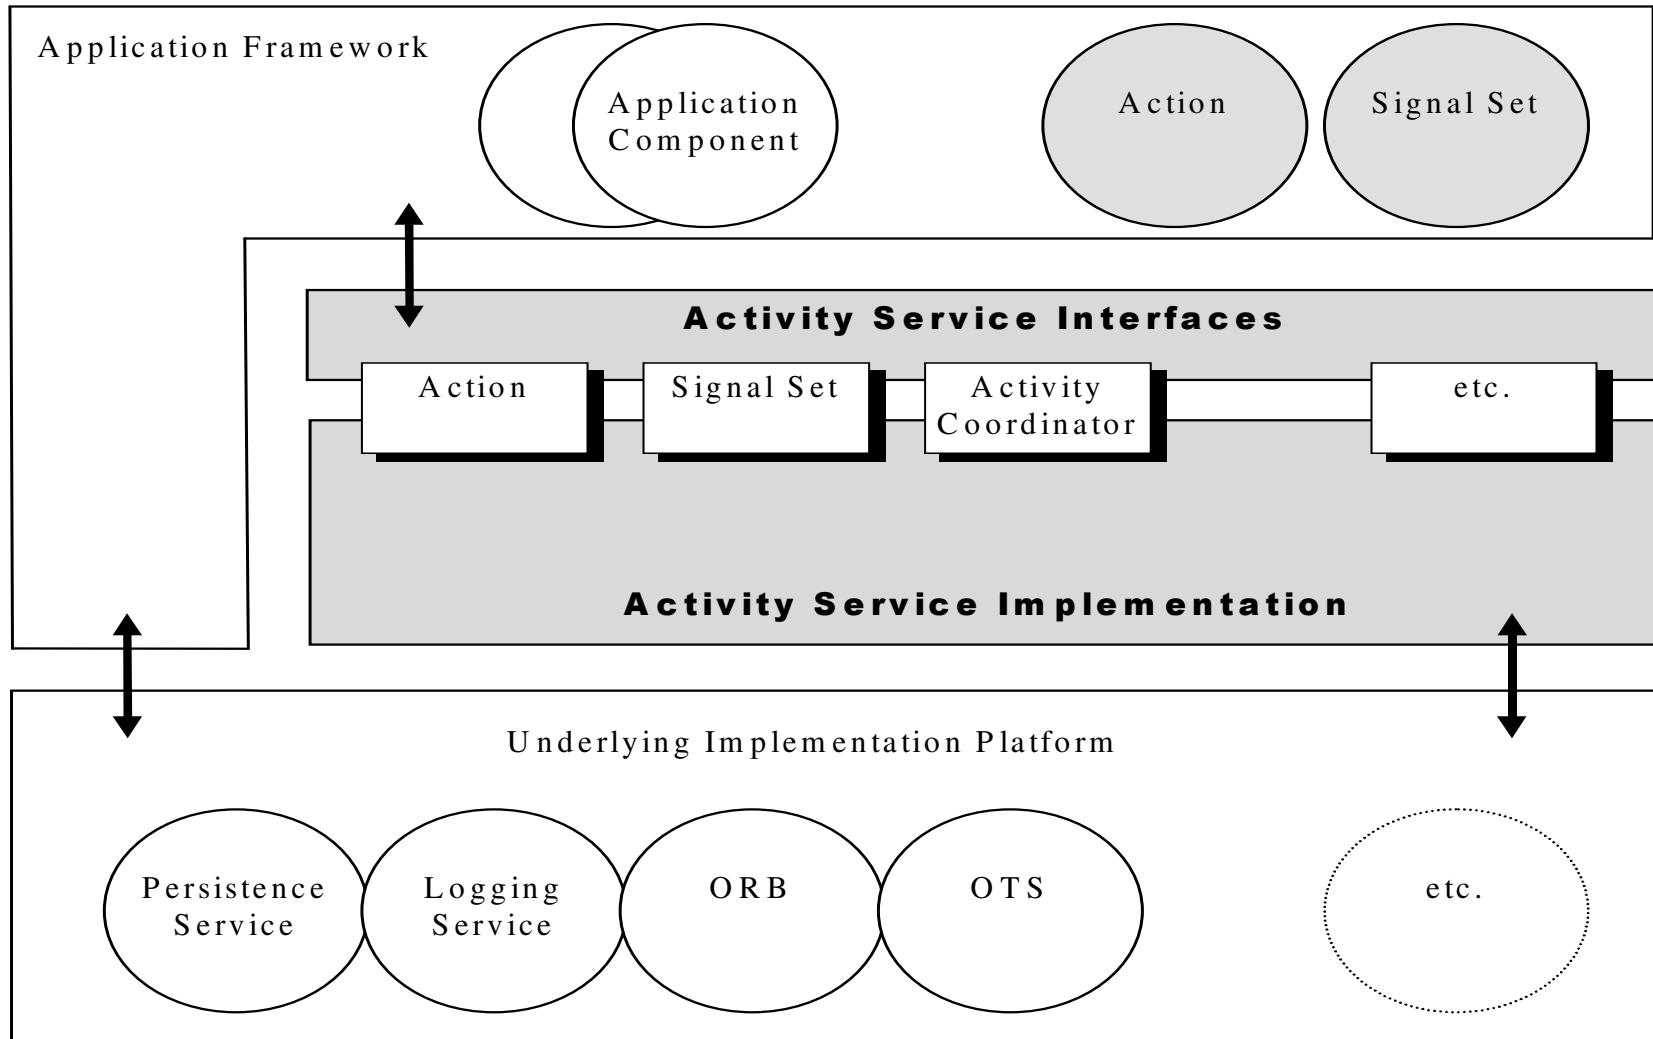

Actions and signals

- ❑ Send “signals” between entities (actions)
 - ☐ Some “signals” are pre-defined
 - ☐ Most are defined by the extended model and dealt with at that level
- ❑ Signal factory is pluggable and adaptable
 - ☐ Responsible for interpreting results of signal processing
- ❑ Infrastructure does not know how to interpret signals or responses to them

Architecture

Future directions

- ❏ New transaction models being proposed
 - ☒ Domain specific (telecoms, banking)
 - ☒ Active area of interesting research
- ❏ Lots of interest within OMG members
 - ☒ Key participants already have requirements
 - ☒ Glue for transaction domains, b2b
- ❏ UML profile for transactions and extended transactions

Conclusions

- ❏ JCP process already in the works
- ❏ OTS-NG
- ❏ General principles be the basis for other environments
 - ☐ Mobile
 - ☐ Web
- ❏ We have the first 100% pure Java implementation
 - ☐ Prototype completed and tested
